# 16-BIT, 750-kHz, UNIPOLAR INPUT, MICRO POWER SAMPLING ANALOG-TO-DIGITAL CONVERTER WITH PARALLEL INTERFACE

## FEATURES

- 750-KSPS Sample Rate
- High Linearity:
  - +0.9 LSB INL Typ, ±1.5 LSB Max
  - −0.4/+0.6 LSB DNL Typ, ±1 LSB Max
- Onboard Reference Buffer and Conversion Clock
- 0 V to 4.096 V Unipolar Inputs
- Low Noise: 88 dB SNR
- High Dynamic Range: 110 dB SFDR
- Very Low Offset and Offset Drift
- Low Power: 130 mW at 750 KSPS
- Wide Buffer Supply, 2.7 V to 5.25 V
- Flexible 8-/16-Bit Parallel Interface
- Direct Pin Compatible With ADS8381/ADS8383
- 48-Pin TQFP Package

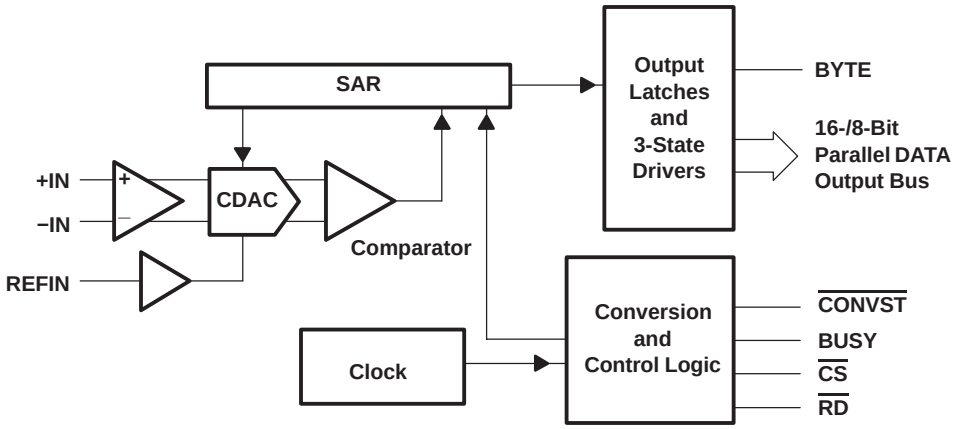
## APPLICATIONS

- Medical Instruments
- Optical Networking
- Transducer Interface
- High Accuracy Data Acquisition Systems
- Magnetometers

## DESCRIPTION

The ADS8371 is an 16-bit, 750 kHz A/D converter. The device includes a 16-bit capacitor-based SAR A/D converter with inherent sample and hold. The ADS8371 offers a full 16-bit interface or an 8-bit bus option using two read cycles.

The ADS8371 is available in a 48-lead TQFP package and is characterized over the industrial −40°C to 85°C temperature range.



Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

## ORDERING INFORMATION

| MODEL | MAXIMUM INTEGRAL LINEARITY (LSB) | MAXIMUM DIFFERENTIAL LINEARITY (LSB) | NO MISSING CODES RESOLUTION (BIT) | PACKAGE TYPE | PACKAGE DESIGNATOR | TEMPERATURE RANGE | ORDERING INFORMATION | TRANSPORT MEDIA QUANTITY |
|---|---|---|---|---|---|---|---|---|
| ADS8371I | ±2.5 | −1/1.5 | 16 | 48 Pin TQFP | PFB | −40°C to 85°C | ADS8371IPFBT | Tape and reel 250 |
| | | | | | | | ADS8371IPFBR | Tape and reel 1000 |
| ADS8371IB | ±1.5 | ±1 | 16 | 48 Pin TQFP | PFB | −40°C to 85°C | ADS8371IBPFBT | Tape and reel 250 |
| | | | | | | | ADS8371IBPFBR | Tape and reel 1000 |

NOTE: For the most current specifications and package information, refer to our website at www.ti.com.

## ABSOLUTE MAXIMUM RATINGS

over operating free-air temperature range unless otherwise noted(1)

| | | UNIT |
|---|---|---|
| Voltage | +IN to AGND | −0.4 V to +VA + 0.1 V |
| | −IN to AGND | −0.4 V to 0.5 V |
| Voltage range | +VA to AGND | −0.3 V to 7 V |
| | +VBD to BDGND | −0.3 V to 7 V |
| | +VA to +VBD | −0.3 V to 2.55 V |
| Digital input voltage to BDGND | | −0.3 V to +VBD + 0.3 V |
| Digital output voltage to BDGND | | −0.3 V to +VBD + 0.3 V |
| Operating free-air temperature range, $T_A$ | | −40°C to 85°C |
| Storage temperature range, $T_{stg}$ | | −65°C to 150°C |
| Junction temperature ($T_J$ max) | | 150°C |
| TQFP package | Power dissipation | $(T_J Max - T_A)/\theta_{JA}$ |
| | $\theta_{JA}$ thermal impedance | 86°C/W |
| Lead temperature, soldering | Vapor phase (60 sec) | 215°C |
| | Infrared (15 sec) | 220°C |

(1) Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

## SPECIFICATIONS

$T_A$ = −40°C to 85°C, +VA = 5 V, +VBD = 3 V or 5 V, $V_{ref}$ = 4.096 V, $f_{SAMPLE}$ = 750 kHz (unless otherwise noted)

| PARAMETER | TEST CONDITIONS | ADS8371IB | | | ADS8371I | | | UNIT |
|---|---|---|---|---|---|---|---|---|
| | | MIN | TYP | MAX | MIN | TYP | MAX | |

## APPLICATION INFORMATION

### MICROCONTROLLER INTERFACING

#### ADS8371 to 8-Bit Microcontroller Interface

Figure 38 shows a parallel interface between the ADS8371 and a typical microcontroller using the 8-bit data bus. The BUSY signal is used as a falling-edge interrupt to the microcontroller.

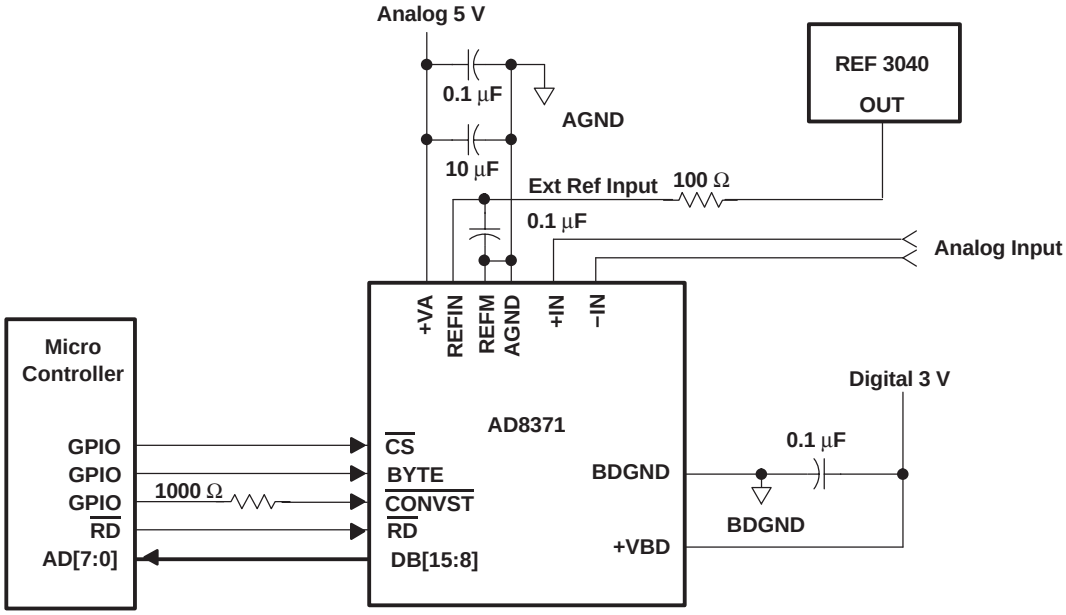

**Figure 38. ADS8371 Application Circuitry**

## PRINCIPLES OF OPERATION

The ADS8371 is a high-speed successive approximation register (SAR) analog-to-digital converter (ADC). The architecture is based on charge redistribution which inherently includes a sample/hold function. See Figure 38 for the application circuit for the ADS8371.

The conversion clock is generated internally. The conversion time of 1.13 μs is capable of sustaining a 750-kHz throughput.

The analog input is provided to two input pins: +IN and −IN. When a conversion is initiated, the differential input on these pins is sampled on the internal capacitor array. While a conversion is in progress, both inputs are disconnected from any internal function.

### REFERENCE

The ADS8371 can operate with an external reference with a range from 2.5 V to 4.2 V. The reference voltage on the input pin 1 (REFIN) of the converter is internally buffered. A clean, low noise, well-decoupled reference voltage on this pin is required to ensure good performance of the converter. A low noise band-gap reference like the REF3040 can be used to drive this pin. A 0.1-uF decoupling capacitor is required between pin 1 and pin 48 of the converter. This capacitor should be placed as close as possible to the pins of the device. Designers should strive to minimize the routing length of the traces that connect the terminals of the capacitor to the pins of the converter. An RC network can also be used to filter the reference voltage. A 100-Ω series resistor and a 0.1-uF capacitor, which can also serve as the decoupling capacitor, can be used to filter the reference voltage.

### ANALOG INPUT

When the converter enters the hold mode, the voltage difference between the +IN and −IN inputs is captured on the internal capacitor array. The voltage on the −IN input is limited between –0.2 V and 0.2 V, allowing the input to reject small signals which are common to both the +IN and −IN inputs. The +IN input has a range of –0.2 V to $V_{ref}$ + 0.2 V. The input span (+IN − (−IN)) is limited to 0 V to $V_{ref}$.

The input current on the analog inputs depends upon a number of factors: sample rate, input voltage, and source impedance. Essentially, the current into the ADS8371 charges the internal capacitor array during the sample period. After this capacitance has been fully charged, there is no further input current. The source of the analog input voltage must be able to charge the input capacitance (45 pF) to an 16-bit settling level within the acquisition time (200 ns) of the device. When the converter goes into the hold mode, the input impedance is greater than 1 GΩ.

Care must be taken regarding the absolute analog input voltage. To maintain the linearity of the converter, the +IN and −IN inputs and the span (+IN − (−IN)) should be within the limits specified. Outside of these ranges, the converter's linearity may not meet specifications. To minimize noise, low bandwidth input signals with low-pass filters should be used.

Care should be taken to ensure that the output impedance of the sources driving the +IN and −IN inputs are matched. If this is not observed, the two inputs could have different setting times. This may result in offset error, gain error, and linearity error which changes with temperature and input voltage.

The analog input to the converter needs to be driven with a low noise, high-speed op-amp like the THS4031. An RC filter is recommended at the input pins to low-pass filter the noise from the source. A series resistor of 15 Ω and a decoupling capacitor of 200 pF is recommended.

The input to the converter is a unipolar input voltage in the range 0 V to $V_{ref}$. The THS4031 can be used in the source follower configuration to drive the converter.

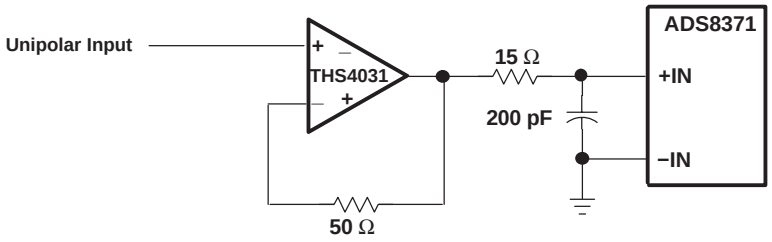

**Figure 39. Unipolar Input to Converter**

In systems where the input is bipolar, the THS4031 can be used in the inverting configuration with an additional DC bias applied to its + input so as to keep the input to the ADS8371 within its rated operating voltage range. This configuration is also recommended when the ADS8371 is used in signal processing applications where good SNR and THD performance is required. The DC bias can be derived from the REF3020 or the REF3040 reference voltage ICs. The input configuration shown below is capable of delivering better than 87-dB SNR and –90-db THD at an input frequency of 100 kHz. In case bandpass filters are used to filter the input, care should be taken to ensure that the signal swing at the input of the bandpass filter is small so as to keep the distortion introduced by the filter minimal. In such cases, the gain of the circuit shown in Figure 40 can be increased to keep the input to the ADS8371 large to keep the SNR of the system high. Note that the gain of the system from the + input to the output of the THS4031 in such a configuration is a function of the gain of the AC signal. A resistor divider can be used to scale the output of the REF3020 or REF3040 to reduce the voltage at the DC input to THS4031 to keep the voltage at the input of the converter within its rated operating range.

## DIGITAL INTERFACE

### Timing And Control

See the timing diagrams in the specifications section for detailed information on timing signals and their requirements.

The ADS8371 uses an internal oscillator generated clock which controls the conversion rate and in turn the throughput of the converter. No external clock input is required.

Conversions are initiated by bringing the $\overline{\text{CONVST}}$ pin low for a minimum of 40 ns (after the 40 ns minimum requirement has been met, the $\overline{\text{CONVST}}$ pin can be brought high), while $\overline{\text{CS}}$ is low. The BUSY output is brought high immediately following $\overline{\text{CONVST}}$ going low. BUSY stays high throughout the conversion process and returns low when the conversion has ended. Sampling starts with the falling edge of the BUSY signal when $\overline{\text{CS}}$ is tied low or starts with the falling edge of $\overline{\text{CS}}$ when BUSY is low.

Both $\overline{\text{RD}}$ and $\overline{\text{CS}}$ can be high during and before a conversion with one exception ($\overline{\text{CS}}$ must be low when $\overline{\text{CONVST}}$ goes low to initiate a conversion). Both the $\overline{\text{RD}}$ and $\overline{\text{CS}}$ pins are brought low in order to enable the parallel output bus with the conversion.

### Digital Inputs

The converter switches from sample to hold mode at the falling edge of the $\overline{\text{CONVST}}$ input pin. A clean and low jitter falling edge is important to the performance of the converter. A sharp falling transition on this pin can affect the voltage that is acquired by the converter. A falling transition time in the range of 10 ns to 30 ns is required to achieve the rated performance of the converter. A resistor of approximately 1000 Ω (10% tolerance) can be placed in series with the $\overline{\text{CONVST}}$ input pin to satisfy this requirement.

The other digital inputs to the ADS8371 do not require any resistors in series with them. However, certain precautions are necessary to ensure that transitions on these inputs do not affect converter performance. It is recommended that all activity on the input pins happen during the first 400 ns of the conversion period. This allows the error correction circuits inside the device to correct for any errors that these activities cause on the converter output. For example, when the converter is operated with $\overline{\text{CS}}$ and $\overline{\text{RD}}$ tied to ground, the signal $\overline{\text{CONVST}}$ can be brought low to initiate a conversion and brought high after a duration not exceeding 400 ns. Figure 41 shows the recommended timing for the $\overline{\text{CONVST}}$ input with $\overline{\text{RD}}$ and $\overline{\text{CS}}$ tied low.

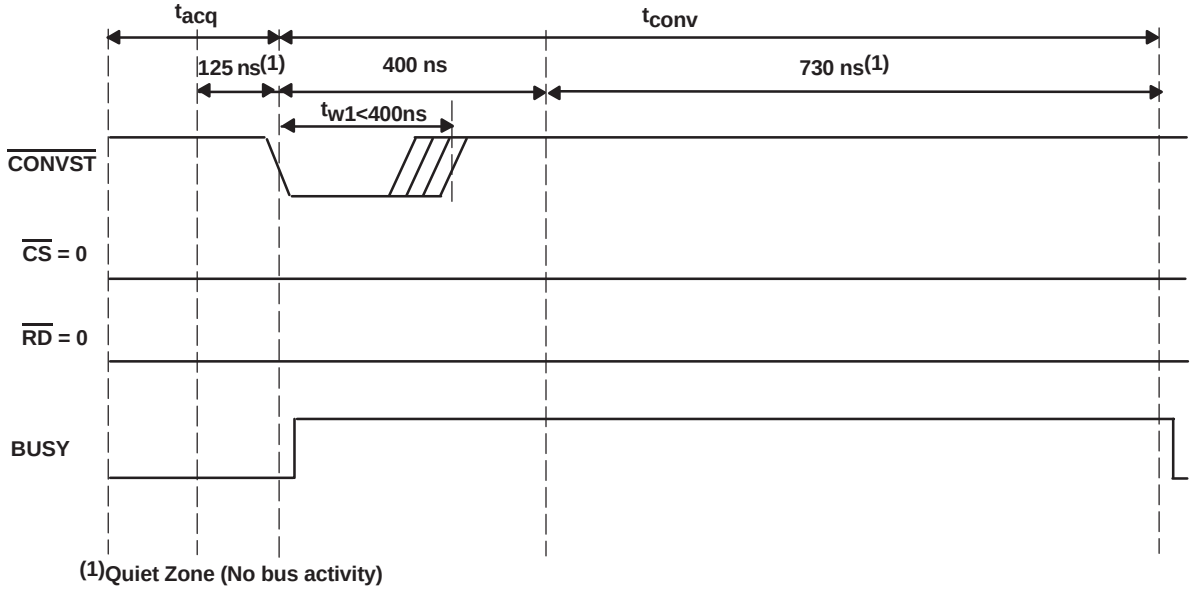

**Figure 41. Timing for $\overline{\text{CONVST}}$ When $\overline{\text{CS}}$ = $\overline{\text{RD}}$ = BDGND**

A similar precaution applies when $\overline{RD}$ is used to three-state the output buffers after a data-read operation. A minimum quite period of 125 ns is also required from the instant the data is changed on the bus (such as the falling or rising edge of $\overline{RD}$, the falling or rising edge of BYTE, and the falling is made available on the data bus pins to the sampling instant (falling edge of $\overline{CONVST}$). Figure 42 shows the timing of the input control signals that allow these conditions to be satisfied.

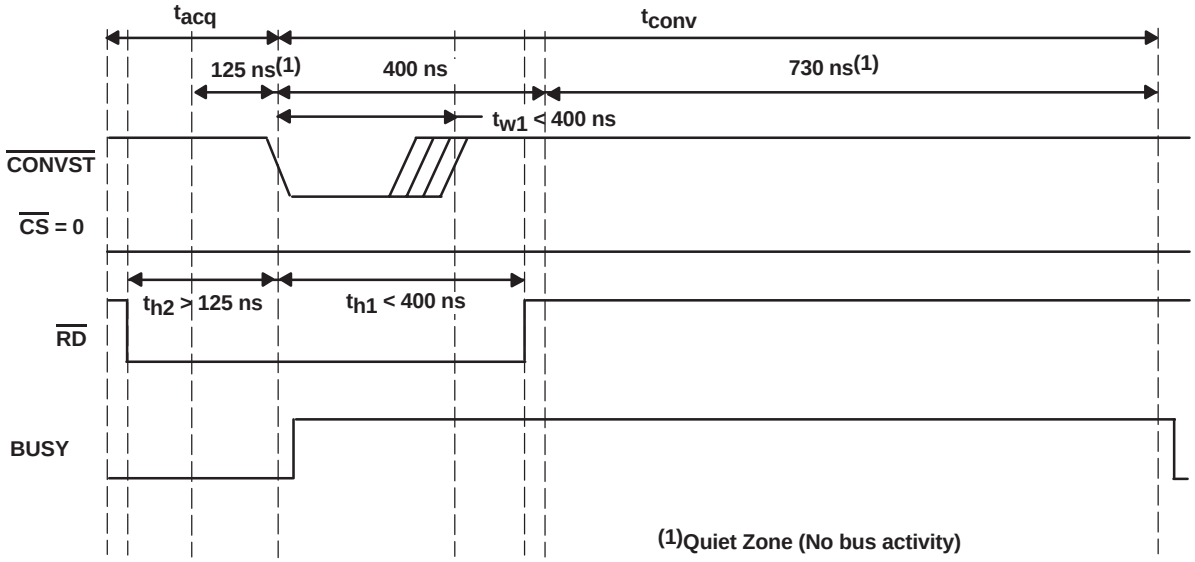

**Figure 42. Bus Activity Split to Avoid Quiet Zone**

If the $\overline{RD}$ pin is brought high to three-state the data buses, the three-stating operation should occur 125 ns before the end of the acquisition phase. Figure 43 shows the recommended timing for using the ADS8381 in this mode of operation. The same principle applies to other bus activities such as BYTE.

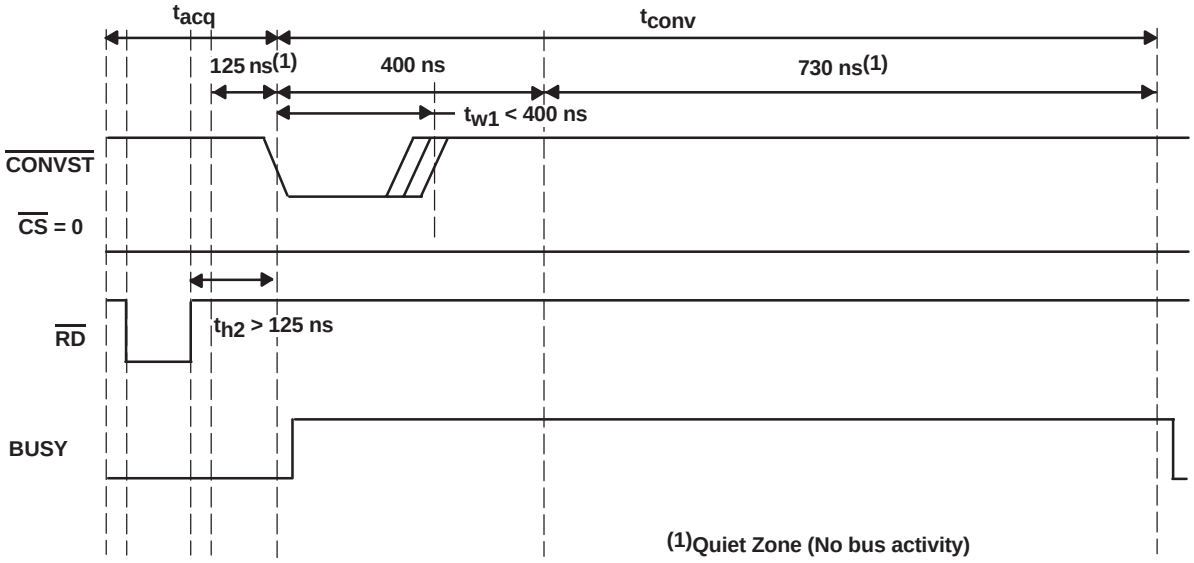

**Figure 43. Read Timing if the Bus Needs to be Three-Stated**

### Reading Data

The ADS8371 outputs full parallel data in straight binary format as shown in Table 1. The parallel output is active when $\overline{CS}$ and $\overline{RD}$ are both low. Any other combination of $\overline{CS}$ and $\overline{RD}$ sets the parallel output to 3-state. BYTE is used for multiword read operations. BYTE is used whenever lower bits on the bus are output on the higher byte of the bus. Refer to Table 1 for ideal output codes.

**Table 1. Ideal Input Voltages and Output Codes**

| DESCRIPTION | ANALOG VALUE | DIGITAL OUTPUT STRAIGHT BINARY | |
|---|---|---|---|
| Full scale range | $(+V_{ref})$ | | |
| Least significant bit (LSB) | $(+V_{ref})/65536$ | BINARY CODE | HEX CODE |
| +Full scale | $(+V_{ref}) – 1$ LSB | 1111 1111 1111 1111 | FFFF |
| Midscale | $(+V_{ref})/2$ | 1000 0000 0000 0000 | 8000 |
| Midscale – 1 LSB | $(+V_{ref})/2 – 1$ LSB | 0111 1111 1111 1111 | 7FFF |
| Zero | 0 V | 0000 0000 0000 0000 | 0000 |

The output data is a full 16-bit word (D15−D0) on DB15–DB0 pins (MSB−LSB) if BYTE is low.

The result may also be read on an 8-bit bus for convenience. This is done by using only pins DB15−DB8. In this case two reads are necessary: the first as before, leaving BYTE low and reading the 8 most significant bits on pins DB15−DB8, then bringing BYTE high. When BYTE is high, the low bits (D7−D0) appear on pins DB15−D8.

These multiword read operations can be done with multiple active $\overline{RD}$ (toggling) or with $\overline{RD}$ tied low for simplicity.

**Table 2. Conversion Data Readout**

| BYTE | DATA READ OUT | |
|---|---|---|
| | DB15−DB8 PINS | DB7−DB0 PINS |
| High | D7−D0 | All one's |
| Low | D15−D8 | D7−D0 |

## RESET

The device can be reset through the use of the combination fo $\overline{CS}$ and $\overline{CONVST}$. Since the BUSY signal is held at high during the conversion, either one of these conditions triggers an internal self-clear reset to the converter.

- Issue a $\overline{CONVST}$ when $\overline{CS}$ is low and internal CONVERT state is high. The falling edge of $\overline{CONVST}$ starts a reset.
- Issue a $\overline{CS}$ (select the device) while internal CONVERT state is high. The falling edge of $\overline{CS}$ causes a reset.

Once the device is reset, all output latches are cleared (set to zeroes) and the BUSY signal is brought low. A new sampling period is started at the falling edge of the BUSY signal immediately after the instant of the internal reset.

## LAYOUT

For optimum performance, care should be taken with the physical layout of the ADS8371 circuitry.

As the ADS8371 offers single-supply operation, it will often be used in close proximity with digital logic, microcontrollers, microprocessors, and digital signal processors. The more digital logic present in the design and the higher the switching speed, the more difficult it is to achieve good performance from the converter.

The basic SAR architecture is sensitive to glitches or sudden changes on the power supply, reference, ground connections and digital inputs that occur just prior to latching the output of the analog comparator. Thus, driving any single conversion for an n-bit SAR converter, there are at least n *windows* in which large external transient voltages can affect the conversion result. Such glitches might originate from switching power supplies, nearby digital logic, or high power devices.

The degree of error in the digital output depends on the reference voltage, layout, and the exact timing of the external event.

On average, the ADS8371 draws very little current from an external reference as the reference voltage is internally buffered. If the reference voltage is external and originates from an op amp, make sure that it can drive the bypass capacitor or capacitors without oscillation. A 0.1-μF bypass capacitor is recommended from pin 1 (REFIN) directly to pin 48 (REFM). REFM and AGND should be shorted on the same ground plane under the device.

The AGND and BDGND pins should be connected to a clean ground point. In all cases, this should be the analog ground. Avoid connections which are too close to the grounding point of a microcontroller or digital signal processor. If required, run a ground trace directly from the converter to the power supply entry point. The ideal layout consists of an analog ground plane dedicated to the converter and associated analog circuitry.

As with the AGND connections, +VA should be connected to a 5-V power supply plane or trace that is separate from the connection for digital logic until they are connected at the power entry point. Power to the ADS8371 should be clean and well bypassed. A 0.1-μF ceramic bypass capacitor should be placed as close to the device as possible. See Table 3 for the placement of the capacitor. In addition, a 1-μF to 10-μF capacitor is recommended. In some situations, additional bypassing may be required, such as a 100-μF electrolytic capacitor or even a Pi filter made up of inductors and capacitors—all designed to essentially low-pass filter the 5-V supply, removing the high frequency noise.

**Table 3. Power Supply Decoupling Capacitor Placement**

| POWER SUPPLY PLANE<br>SUPPLY PINS | CONVERTER ANALOG SIDE | CONVERTER DIGITAL SIDE |
|---|---|---|
| Pin pairs that require shortest path to decoupling capacitors | (4,5), (8,9), (10,11), (13,15), (43,44), (45,46) | (24,25) |
| Pins that require no decoupling | 12, 14 | 37, 38 |
